

SweynTooth: Unleashing Mayhem over Bluetooth Low Energy

Matheus E. Garbelini¹; Sudipta Chattopadhyay¹; Chundong Wang¹

¹Singapore University of Technology and Design

1 Introducing SWEYNTOOTH

The Bluetooth Low Energy (BLE) is a wireless communication technology specially designed to prolong battery life of devices with different power consumption and usage capabilities. BLE consists of a set of many standardised protocols that provide remote connectivity and security between a simple device (peripheral) and the user's device (central) which is usually a smartphone or a notebook. The relevant interaction between both devices is presented in Figure 1.

SWEYNTOOTH captures a family of **12 vulnerabilities** (more under non-disclosure) across different BLE software development kits (SDKs) of six major system-on-a-chip (SoC) vendors. The vulnerabilities expose flaws in specific BLE SoC implementations that allow an attacker in radio range to trigger **deadlocks, crashes** and **buffer overflows** or **completely bypass security** depending on the circumstances.

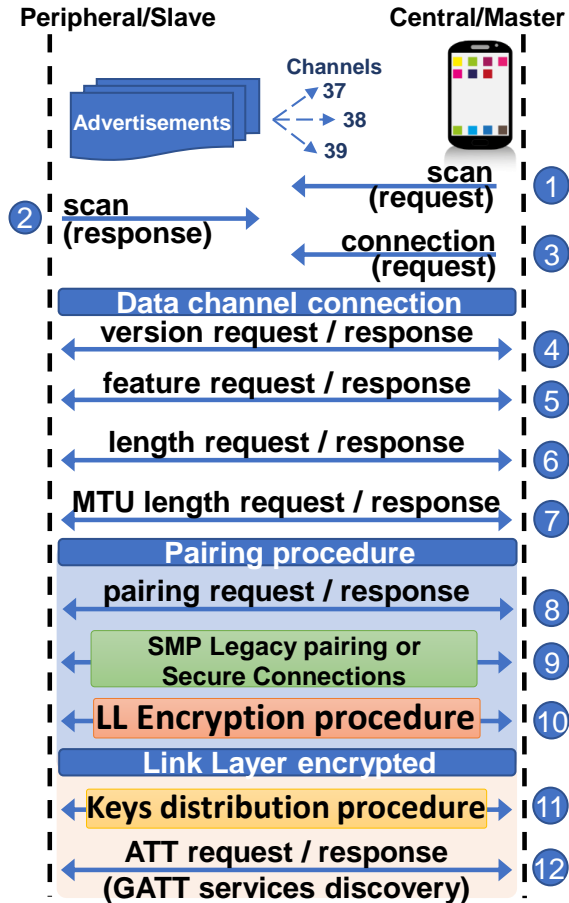

Figure 1: BLE messages exchange diagram

SWEYNTOOTH potentially affects IoT products in appliances such as smart-homes, wearables and environmental tracking or sensing. We have also identified several medical and logistics products that could be affected.

As of today, SWEYNTOOTH vulnerabilities are found in the BLE SDKs sold by major SoC vendors, such as **Texas Instruments, NXP, Cypress, Dialog Semiconductors, Microchip, STMicroelectronics** and **Telink Semiconductor**. *By no means, this list of SoC vendors is exhaustive in terms of being affected by SWEYNTOOTH.* We have followed responsive disclosure during our discovery, which allowed almost all SoC vendors to publicly release their respective patches already. However, a substantial number of IoT products relying on the affected SoCs for BLE connectivity will still need to independently receive patches from their respective vendors, as long as a firmware update mechanism is supported by the vendor.

SWEYNTOOTH highlights concrete flaws in the BLE stack certification process. We envision substantial amendments to the BLE stack certification to avoid SWEYNTOOTH style security flaws. We also urge SoC vendors and IoT product manufacturers to be aware of such security issues and to initiate focused effort in security testing.

A proper classification of the vulnerability set is presented in the next section.

1.1 Types of vulnerabilities

We have classified the SWEYNTOOTH vulnerabilities according to their types and their behaviours on the affected BLE devices.

- **Crash:** Vulnerabilities in this category can remotely crash a device by triggering hard faults. This happens due to some incorrect code behaviour or memory corruption, e.g., when a buffer overflow on BLE reception buffer occurs. When a device crash occurs, they usually restart. However, such a restart capability depends on whether a correct hard fault handling mechanism was implemented in the product that uses the vulnerable BLE SoC.
- **Deadlock:** Deadlocks are vulnerabilities that affect the availability of the BLE connection without causing a hard fault or memory corruption. Usually they occur due to some improper synchronisation between user code and the SDK firmware distributed by the SoC vendor, leaving the user code being stuck at some point. Crashes originated from hard faults, if not properly handled, can

become a deadlock if the device is not automatically restarted. In most cases, when a deadlock occurs, the user is required to manually power off and power on the device to re-establish proper BLE communication.

- **Security Bypass:** This vulnerability is the most critical one. This is because the vulnerability allows attackers in radio range to bypass the latest secure pairing mode of BLE, i.e., the *Secure Connections* pairing mode [12]. In summary, after the bypass is completed, an attacker in the radio range has arbitrary read or write access to device’s functions. These functions, in turn, are only meant to be accessed by authorised users.

The summary of our findings and the affected vendors is depicted in Table 1.

Table 1: Vulnerabilities type and affected vendors

Type	Vulnerability Name	Affected Vendors	CVE
Crash	Link Layer Length Overflow	Cypress NXP	CVE-2019-16336 (6.1) CVE-2019-17519 (6.1)
	Truncated L2CAP	Dialog Semiconductors	CVE-2019-17517 (6.3)
	Silent Length Overflow	Dialog Semiconductors	CVE-2019-17518 (6.4)
	Public Key Crash	Texas Instruments	CVE-2019-17520 (6.6)
	Invalid L2CAP Fragment	Microchip	CVE-2019-19195 (6.8)
	Key Size Overflow	Telink Semiconductor	CVE-2019-19196 (6.9)
Deadlock	LLID Deadlock	Cypress NXP	CVE-2019-17061 (6.2) CVE-2019-17060 (6.2)
	Sequential ATT Deadlock	STMicroelectronics	CVE-2019-19192 (6.7)
	Invalid Connection Request	Texas Instruments	CVE-2019-19193 (6.5)
Security Bypass	Zero LTK Installation	Telink Semiconductor	CVE-2019-19194 (6.10)

2 Vulnerable BLE chips

Table 2 lists the affected SoCs and the respective SDK versions where the vulnerabilities were found. The qualification ID of each SoC, attributed to vendors after their SDK is certified, allows to search for products using the SoC connected to such ID on the Bluetooth Listing Search site [14]. A basic search on this site yields about **480 products listings using the affected SoCs** from Table 2. Each listing may contain multiple products from the same vendor, which further increases the total number of different products affected. This does not mean, however, that all products are guaranteed to be affected. This is because the impact of SWEYNTTOOTH vulnerabilities depends on how the product software handles BLE communication and how much it relies on affected SoCs to operate.

2.1 Attacks on IoT

The exploitation of the vulnerabilities translates to dangerous attack vectors against many IoT products released in 2018-2019. At first glance, most of the vulnerabilities affect product’s availability by allowing them to be remotely restarted, deadlocked or having their security bypassed. In order to raise awareness of the threats and risks of potentially vulnerable products already on the market, we have performed attacks on five representative IoT products which use the affected

Table 2: Vulnerabilities and SDK versions of the affected SoCs.* indicates extra affected SoCs reported by the vendor not tracked by our team.

Vuln.	SoC Vendor	SoC Model	SDK Ver.	Qualification ID(s)
BLE Version 5.0/5.1				
6.1,6.2	Cypress (PSoC 6)	CYBLE-416045	2.10	99158
6.5,6.6	Texas Instruments	CC2640R2	3.30.00.20	94079
6.9,6.10	Telink	TLSR8258	3.4.0	92269, 136037
6.7	STMicroelectronics	WB55	1.3.0	111668
6.7	STMicroelectronics	BlueNRG-2	3.1.0	87428, 106700, 94075
6.4	Dialog	DA1469X*	10.0.6	100899
6.3	Dialog	DA14585/6*	6.0.12.1020	91436
BLE Version 4.2				
6.1,6.2	Cypress (PSoC 4)	CYBL11573	3.60	62243, 136808, 79697, 82951, 79480
6.1,6.2	NXP	KW41Z	2.2.1	84040
6.4	Dialog	DA14680	1.0.14.X	87407, 84084, 71309, 75255
BLE Version 4.1				
6.5	Texas Instruments	CC2540	1.5.0	23454, 127418
6.3	Dialog	DA14580	5.0.4	83573
6.8	Microchip	ATSAMB11	6.2	73346

Table 3: Products verified to be vulnerable

Product	Category	BLE SoC	Vulnerability	Impact
Eve Energy	Smart Home	DA14680	(6.4) Silent Length Overflow	Crash
August Smart Lock	Smart Home	DA14680	(6.4) Silent Length Overflow	Crash
Fitbit Inspire	Wearables	CY8C68237	(6.1) LL Length Overflow (6.2) LLID Deadlock	Crash
CubiTag	Gadget Tracking	CC2640R2	(6.6) Public Key Crash	Deadlock
eGeeTouch TSA Lock	Security	CC2540	(6.5) Invalid Connection Request	Deadlock

SoCs (cf. Table 2) as their main processor. These products are shown in Figure 2.

Figure 2: An illustration of some vulnerable products.

- **Wearables: Fitbit Inspire** - Latest 2018 smartwatches line-up from FitBit uses the Cypress PSoC 6 as the main processor. Hence they are vulnerable to *Link Layer Overflow* and *LLID Deadlock*. To verify what happens to the wearable when both issues are exploited, we have sent malicious packets to the Fitbit Inspire smartwatch (Figure 2a) through the BLE communication channel.

Once the malicious packets are sent to the device, it is possible to trigger either a buffer overflow in device’s memory or deadlock its bluetooth stack temporarily. The former attack (exploiting *Link Layer Overflow*) immediately restarts the device whereas the latter (exploiting

LLID Deadlock) disables its bluetooth advertisement for about 27 seconds before the smartwatch is automatically restarted by the firmware.

In summary, the vulnerabilities only seem to temporarily block the availability of Fitbit. However, the *Link Layer Length Overflow* is a serious threat by itself. Specifically, such an overflow is a potential front door to remote execution once an attacker knows the memory layout of the firmware by means of reverse engineering it. Similar behaviour is expected in Fitbit Charge 3 and Ace 2. This is because they embed Cypress PSoC 6 as their main processor.

- **Smart Home: Eve Systems** - Many smart home products from Eve Systems are vulnerable due to their reliance on Dialog DA14680 as the main processor. For instance, Eve Light Switch, Eve Motion MKII, Eve Aqua, Eve Thermo MKII, Eve Room, Eve Lock, etc, are all prone to *Silent Length Overflow*. Specifically, it is possible to crash such devices by sending a specific packet which overflows device’s reception buffer. When an attack occurs, the user can immediately experience her smart products restarting or getting unstable. As an example, when performing the *Silent Length Overflow* against the **Eve Energy** (Figure 2b), the power on the smart plug is cut off when its processor crashes and restarts. As a consequence, we can momentarily cut the power to anything connected in the socket by just sending a malicious packet within radio range of the smart socket. Furthermore, an attacker can use this simple attack to cause real damage to some equipment connected to the plug by intermittently cutting its power.

August Smart Lock - We have verified that the *Silent Length Overflow* also affects the popular **August Smart Lock** (Figure 2c). Such a smart lock remotely controls access to house doors. Hence, it is advisable that users update their affected devices as soon as possible. This is to avoid a worst-case exploit, which could grant access control to a thief by means of remote execution.

- **Tracking Gadget: CubiTag** - The *CubiTag* Bluetooth tracker is a popular product that tracks the belongings of a user (Figure 2d). When the tracker is near an object of interest, it can be found by using a mobile app, which searches for the tracker and starts an alarm on the tracker. As a result, the user can hear the alarm and find the object. However, *CubiTag* relies on a vulnerable TI CC2640R2 SDK. Out of two vulnerabilities on this SDK, only the *Public Key Crash* affects availability of CubiTag. The CubiTag immediately stops advertising itself and is never found by the mobile app again; hence it is deadlocked. *The CubiTag device only works again by manually opening it with a screwdriver and re-inserting its battery*. This is for the tracker SoC to reboot properly

and to establish normal BLE connection.

- **Smart Locks: eGee Touch** - The eGee Touch, shown in Figure 2e, is a smart luggage lock that can be remotely locked or unlocked through a smartphone app. During our tests, as the device uses the TI CC2540 SoC, we could lead the smart lock in a deadlock state by exploiting the *Invalid Connection Request* vulnerability. When an attack is carried out, the device hangs and the user needs to manually press the *power on* button on the smart lock to re-interact with it. This is not a critical problem by itself. However, the worst-case scenario occurs when the user enables continuous advertisement on the smart lock. This prevents the device to automatically restart after the attack, hence its batteries must be re-inserted to reboot its processor and restore functionalities back to normal.

2.2 Other potentially vulnerable products

As mentioned in Section 2, the vulnerabilities discovered by our team are likely to affect a substantial number of products that rely on the affected SoCs. While it is difficult to confirm the reach of such vulnerabilities for every product out in the wild, we provide an overview of the types of products potentially affected by SWEYNTTOOTH using the Bluetooth Listing Search site [14]. Figure 3 captures the total number of products listings using the affected SoCs as of 8th February, 2020.

Figure 3: Number of product listings for each SoC affected as of February 8, 2020.

While the majority of products are listed under CC2540, we note several critical BLE products using the other affected SoC vendors. These products are applied to **logistics, medical, consumer electronics, smart home, wearables** and other fields. Although it is impractical for our team to verify such a large number of products using the affected SoCs, we outline some of the most notorious or popular products found on Bluetooth Listing website [14]. These critical products are shown in Table 4.

Table 4: Some notorious products using SoCs affected by SWEYNTTOOTH. The declaration ID references each product on the Bluetooth Listing Search [14].

Product Vendor	Product Model	SoC Model	Category	Declaration ID
Swipbox International A/S	IN180-series	KW41Z/31Z	Logistics	D043799
VivaChek Laboratories, Inc.	Blood Glucose Meter (many more)	DA14580	Medical	D049092
Medtronic Inc.	Azure XT DR MRI (many more)	DA14580	Medical	D047941
Syqe Medical Ltd	Syqe Inhaler v01	DA14580	Medical	D046866
Anhui Huami Info. Tech. Co., Ltd.	Amazfit Bip Lite, A1915	DA14580	Wearables	D047941
	Mi Band 3 NFC

	Charge 3			
Fitbit, Inc.	Ace 2 (few more)	PSOC 6	Wearables	D039792
RESIDEO TECHNOLOGIES, INC.	Buoy Device	ATSAMB11	Indoor/Outdoor Monitoring	D029728
	Mi Wireless Mouse			
Xiaomi Inc.	Mi Silent Mouse	TLSR 82xx	Consumer Electronics	D046746
Samsung Electronics Co., Ltd.	Smart Lightning Module, SLM-A-BD4	TLSR 82xx	Modules	D042305
Qingping Technology (Beijing)	Qingping Bluetooth Alarm Clock	TLSR 82xx	Smart Home	D048743

The most critical devices that could be severely impacted by SWEYNTTOOTH are the medical products. VivaCheck Laboratories, which manufacture Blood Glucose Meters, has many products listed to use DA14580. Hence all these products are potentially vulnerable to the Truncated L2CAP attack. Even worse, Syqe Medical Ltd. and their programmable drug delivery inhalation platform (**Syqe Inhaler v01**) is affected alongside the latest pacemaker related products from Medtronic Inc. While our team did not verify the extent to which SWEYNTTOOTH affects such devices (e.g. the impact of remotely restarting such devices or remote code execution in the worst case), it is highly recommended that such companies update their firmware. This is to avoid any situation that could pose life threatening risks to the patients using the respective medical products. Unfortunately, the security issue found in Dialog DA14580 is still unpatched (cf. Table 5). Nonetheless, Dialog is working on an internal security patch for DA14580 and will release it for general public in the next SDK release. More details about patches are mentioned in Section 3.

Another complication arises for the IN180-13 from Swipbox International. This product uses the vulnerable KW41Z SoC from the vendor NXP semiconductor. According to the company page [15], the battery operated product is an automatic parcel locker and has no display. Instead, it relies entirely on a smartphone application communicating via BLE to unlock the parcel sent to the recipient. Similarly to what

happens to CubiTag, the KW41Z is vulnerable to a deadlock (LLID Deadlock). The KW41Z LLID deadlock vulnerability is particularly easy to trigger and allows an attacker in radio range to simply block anyone to connect to the parcel locker (unless the the parcel locker is automatically restarted). Fortunately, NXP has already released patches for the two vulnerabilities affecting KW41Z. Other potentially vulnerable popular products include vendors such as August Home, Eve Systems, Samsung and Anhui Huami Information Technology, among others.

It is worthwhile to note that the list in Table 4 is not exhaustive. Thus, we recommend each product vendor to update the SDK firmware of their products to the latest if available or contact their SoC vendor to enquire on the status of the patch.

3 Security Patches

Most of the affected vendors have released patches for their respective SoCs. One can get the latest patches by downloading the newest SDK of each vendor referenced in Table 5. Product vendors (who use the affected SoCs), on the other hand, are being independently contacted by each SoC vendor to inform about the security patches. However, we note that some SoCs did not receive a patch from their vendor yet. This is the case for Dialog, Microchip and STMicroelectronics. We will be updating this section once vendors release the security

patches for the affected SoCs.

We urge action from vendors due to the reliance of the BLE IoT market on such unpatched SoCs. For example, **August Home Inc** and **Eve Systems** products rely almost entirely on **DA14680**, which is still *unpatched* even after a responsive disclosure period of more than 90 days.

During our contact with Dialog, they have confirmed that a patch is planned in the next SDK release for the affected SoCs. We were also informed that the reason of such delay is due to the affected code being stored in the read-only-memory (ROM) of such SoCs. Thus, the respective vulnerable BLE stack cannot be modified and it requires complex workarounds for publicly releasing a patch.

Table 5: Patches available by the SoC vendors.

SoC Vendor	SoC Model	Vendor Patches
Cypress (PSoC 6)	CYBLE-416045	[4] BLE_PDL 2.2
Cypress (PSoC 4)	CYBL11573	[3] BLE Component 3.63
NXP	KW41Z	[8] 2.2.1 (2019-11-28)
Texas Instruments	CC2640R2	[7] v3.40.00.10
Texas Instruments	CC2540	[6] v1.5.1
Telink	TLSR8258	[16] v3.4.0 (SMP fix)
Telink	TLSR8232	[18] v1.3.0 (SMP fix)
Telink	TLSR826x	[17] v3.3 (SMP fix)
Dialog	DA1469X	[9] 10.0.8.105
Dialog	DA14585/6	Unpatched (End March 2020)
Dialog	DA14680	Unpatched (End February 2020)
Dialog	DA14580	Unpatched (End March 2020)
Microchip	ATSAMB11	Unpatched
STMicroelectronics	WB55	Unpatched
STMicroelectronics	BlueNRG-2	Unpatched

4 Non-compliance in the wild!

In recent years, Bluetooth design has been under scrutiny due to several security flaws such as KNOB [1], BlueBorne [10] and Invalid ECC Attack [2]. In contrast, little to no research has been carried out on the security of the diverse Bluetooth implementations out in the wild. The current practice is to leave the implementation tests to the Bluetooth certification process. This is with the mindset that once the design is sound, hardly anything can break in the implementation of the Bluetooth stack.

Our findings expose some fundamental attack vectors against certified and recertified BLE Stacks which are supposed to be “safe” against such flaws. We carefully investigated the reasons that might explain the presence of SWEYNTOOTH vulnerabilities on the affected SoCs. We believe this is due to the imposed isolation between the link layer and other Bluetooth protocols, via the Host Controller Interface (HCI) protocol [12]. While such a strategy is reasonable for hardware compatibility, this adds complexity to the implementation. Moreover, it overly complicates the strategies to systematically and comprehensively test Bluetooth protocols. Specifically, during testing, it is complex to send arbitrary Link Layer messages during other protocol message exchanges.

Such added complexity is likely the reason for inadequate security testing of BLE stack implementation.

We carefully read and investigated relevant parts of the Controller and Host volume of the Core Specification, which allow us to understand the main interaction of two devices (c.f., Figure 1). A natural question that arises for anyone looking a sequence diagram of the overall pairing procedure is “*what happens if the LL encryption starts in the middle of the pairing procedure?*”. It can be argued that the Zero LTK installation, Key size overflow and Public Key Crash flaws were facilitated due to this question not being answered on the Core Specification itself, leaving it for vendors to decide how to handle such situation. When attempting to answer this question, we have received highly different behaviours across most SoCs we have tested. In addition, several other implementation details, which are explicitly imposed by the Core Specification [13], are also not followed by SoC vendors in reality.

It is worthwhile to mention that every SoC BLE SDK goes through the certification process before going into market. Thus, our findings expose that improvements should be made on the certification process to avoid at least *simple* deviations such as the LLID deadlock: *It takes exactly one field to be zero to lead the device into a deadlock*. Furthermore, devices from Telink responds to version requests multiple times, going against [Vol 6] Part B, Section 5.1.5 of Core Specification [13], which defines that the peripheral should only respond a version request a single time during the same central-peripheral connection. Similarly, all devices we have tested accept a connection request with the “hopIncrement” field value of less than five. This behaviour goes against [Vol 6] Part B, Section 2.3.3.1, which dictates the valid range of such field to be within 5-16. Moreover, all the vulnerabilities we have discovered go against [Vol 1] Part E, Section 2.7 (Responding to malformed behaviour). This part of the specification provides directives and few examples to handle invalid or malformed packets.

In conclusion, we strongly believe that the Bluetooth SIG should improve and significantly expand Section 2.7 (the section is less than one page!!!) and add more basic tests to the Bluetooth certification to avoid zero-day vulnerabilities such as the ones captured by SWEYNTOOTH.

5 Why SWEYNTOOTH?

The insight behind the name SweynTooth arrives from Sweyn Forkbeard, the son of King Harald Bluetooth (after whom the Bluetooth Technology was originally named). Sweyn revolted against Harald Bluetooth and this forced King Harald to his exile. The exile lead to the death of King Harald shortly. We envision that if SweynTooth style vulnerabilities are not appropriately handled by BLE vendors, then the technology can become a breeding ground for attackers. This may, in turn, lead the Bluetooth technology to be obsolete.

The SweynTooth logo captures a variation of the original Bluetooth logo written in the Runic alphabet. From the Runic alphabet, the "S" of Sweyn and "B" of Bluetooth are combined to design the logo. Moreover, the "S" in the SweynTooth logo visually captures that the arm of "H" is broken in the Bluetooth logo.

6 Detailed Description

In this section, we provide a detailed description of each vulnerability, the affected system-on-chip (SoC) models and the SDKs.

6.1 Link Layer Length Overflow (CVE-2019-16336, CVE-2019-17519)

The *Link Layer Length Overflow* vulnerability was identified in *Cypress PSoC4/6 BLE Component 3.41/2.60* (CVE-2019-16336) and *NXP KW41Z 3.40 SDK* (CVE-2019-17519). Both implementations are susceptible to the same vulnerability. Such a vulnerability allows attackers in radio range to trigger a buffer overflow by manipulating the *LL Length Field*. The overflow occurs when the attacker, acting as the central device, sends a packet to the peripheral, which is padded to include much more bytes than expected from its type (opcode). An example is shown in Figure 4. In this case, a version request is just five bytes of length, but can be falsely extended to 247 bytes when *LL Length field* value is increased. When the underlying BLE stack processed such a packet, more bytes than the expected are allocated in memory, which caused instabilities and ultimately crashing the peripheral.

Impact: This vulnerability initially causes denial of service (DoS). However, due to its characteristic, attackers could reverse engineer products firmware to possibly leverage remote execution. A concrete evidence of this risk is exemplified by the BleedingBit vulnerability [5], which allowed remote execution on certain Texas Instruments devices by means of manipulating the same *LL length* field, albeit in a more constrained context. Specifically, BleedingBit exploited the central implementation of the SoC during advertisement phase.

6.2 Link Layer LLID deadlock (CVE-2019-17061, CVE-2019-17060)

This critical, yet simple vulnerability can render Cypress (CVE-2019-17061) and NXP devices in a *deadlock* state (CVE-2019-17060). We have discovered that if a *Cypress PSoC4/6* or *NXP KW41Z* device receives a packet with the *LLID field* cleared, then both devices simply enter in a faulty state. Specifically, this state prevents the BLE stack from working correctly in posterior connections. The details of the vulnerability are shown in Figure 5. It turns out that this

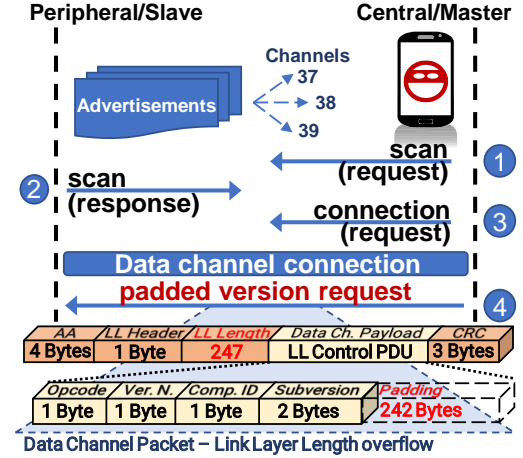

Figure 4: Link Layer Length Overflow vulnerability

attack confuses the SDK implementation in a manner that any received packet from the central is handled improperly or simply ignored. For example, NXP KW41Z peripheral may send responses completely out of order to the central. In addition, no hard faults are triggered in the firmware of the device. This, in turn, prevents auto recovery by means of simply employing watchdog timer on the product's firmware.

Impact: The availability of BLE products is critically impaired, requiring the user to manually perform a power cycle on the product to re-establish BLE communication. Further complication arises, as the peripheral continues to advertise itself after the attack. This makes it difficult for the user to even notice the existence of the problem. The availability issue is only exposed when the user connects to the peripheral, revealing a never ending connection or pairing process.

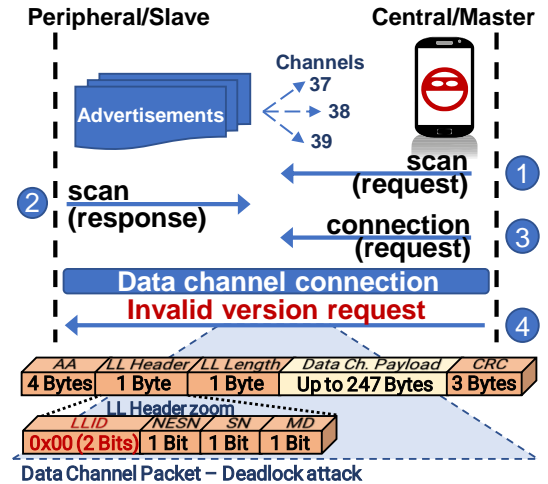

Figure 5: Link Layer LLID deadlock vulnerability

6.3 Truncated L2CAP (CVE-2019-17517)

The *Truncated L2CAP* vulnerability is present on *Dialog DA14580* devices running *SDK 5.0.4* or earlier. The flaw results due to a lack of checks during processing an L2CAP packet. If the total length of the packet (i.e. *LL Length*) has a value lower than *L2CAP Length + 4* for a valid payload, then the truncated bytes are copied beyond the underlying reception buffer. Figure 6 shows an example of a maximum transmission unit (MTU). The MTU captures a length request, which has *LL Length* of seven bytes and *L2CAP Length* of three bytes. If the peripheral receives a malicious MTU length request with *LL Length* of five bytes instead, the L2CAP reception buffer is overflowed by two bytes (i.e. $L2CAP\ Length + 4 - LL\ Length$). Therefore, the attacker can selectively choose the number of bytes to overflow by sending the correct L2CAP payload and the malformed *LL Length* combination to the peripheral.

Impact: An attacker in radio range can use this attack to perform denial of service and crash the device. However, a careful sequence of packets could be sent by the attacker to force the peripheral into writing certain contents to peripheral memory adjacent to the L2CAP reception buffer. In the worst-case scenario, this attack could be a front door to perform remote execution on products using *Dialog DA14580* SoC.

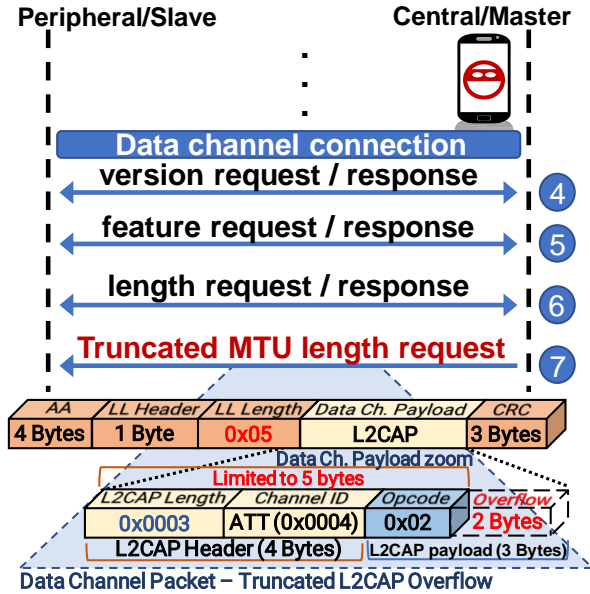

Figure 6: Truncated L2CAP vulnerability

6.4 Silent Length Overflow (CVE-2019-17518)

This attack is similar to *Link Layer Length Overflow* (cf. Section 6.1). In *Dialog DA14680* devices, it was identified that the peripheral responded to packets from the central with

unexpectedly large *LL Length*. While this behaviour is not compliant to BLE Core specifications [12], it does not appear to affect the peripheral at first. Nonetheless, when a certain packet payload with higher than expected *LL Length* is sent, the peripheral crashes. This indicates that an overflow on the reception buffer had occurred for certain packet types such as pairing request.

Impact: An attacker in radio range can mostly use this attack to perform denial of service and crash the device. Given that a buffer overflow is being triggered depending on the packet, a remote execution scenario is a possibility. Furthermore, the SoCs affected by this vulnerability are known to be used in a large number of smart home products, which increases the reachability and risk of a more serious exploit of this vulnerability.

6.5 Invalid Connection Request (CVE-2019-19195)

We identified that sample applications provided in *Texas Instruments CC2640R2 BLE-STACK SDK* (v3.30.00.20 and prior) and *CC2540 SDK* (v1.5.0 and prior) do not properly handle some connection parameters when the central attempts a connection to the peripheral. Instead, the peripheral creates a connection with the central, but fails at a later stage and moves the peripheral state to idle (i.e., stops advertisement). If the idle state is not handled correctly in the product's code, the device does not go back to the advertisement stage again.

During the initial phase of a BLE connection, the central device scans for advertisements packets from the peripheral and sends a connection request packet, which contains relevant parameters such as connection *interval* and *timeout*. These two parameters control the cadence of packet exchange and timeout between peripheral and the central device, respectively. Their values must represent a non-zero time period in *milliseconds* when multiplied by a factor of **1.25**. However, if the central device sends an invalid connection request with the fields *interval* or *timeout* as zero, then the peripheral stops advertisement. During reception of an invalid connection request, the BLE stack sends a connection request fail event to the application code (`bleGAPConnNotAcceptable`) and upon receiving this fail status, the sample application enters in idle state by default, thus stopping advertisements. This behaviour is not the flaw alone, as idle state is a common state in BLE and should be handled by the application, due to other state transitions that can occur during application operation.

Nevertheless, we have discovered that this state change under reception of invalid parameters is not sufficiently documented in TI SDK, which may lead product developers to not handle idle state. The mishandling of this state can lead products such as eGeeLock to stop advertisement and hence requiring user intervention. An illustration of this attack is given in Figure 7.

Interestingly, *CC2540* also accepts connection requests with packet length lower than expected (truncated), which triggers the same behaviour (i.e., Figure 7) due to its implementation assuming zero bytes for truncated fields.

Impact: An attacker in radio range can exploit the phenomenon observed in Figure 7 to easily perform DoS in products using the vulnerable SoCs. Furthermore, if the product vendor does not implement mechanisms to detect such a faulty behaviour, the device can be driven into a deadlock state. This, in turn, requires the user to manually restart the device. In general, the impact on such affected products is similar to the *LLID Deadlock* (cf. Section 6.2).

6.6 Unexpected Public Key Crash (CVE-2019-17520)

This vulnerability was found on Texas Instruments *CC2640R2* BLE-STACK-SDK (v3.30.00.20 and prior versions). Specifically, the vulnerability is present in the implementation of the legacy pairing procedure which is handled by the Secure Manager Protocol (SMP) implementation. When the peripheral performs the legacy pairing procedure, it is possible to cause a hard fault in device's memory by sending an SMP public key packet before the SMP pairing procedure starts (Step 9 in Figure 1). Normally, the peripheral should ignore the reception of a public key if secure connection is not enabled in the *pairing request/response* exchange. During our coordination with the vendor, Texas Instruments informed us that the hard fault is triggered because the peripheral accepts the public key and tries to copy it to a null target address. Normally, this address corresponds to a valid allocated buffer if secure connection is properly indicated during the *pairing request/response* process. We illustrate the vulnerability in Figure 8 (SC means secure connection).

Impact: An attacker in radio range can exploit the aforementioned behaviour to perform DoS and possibly restart products using the *CC2640R2* SoC for the main application. On the

bright side, it is not possible to perform a buffer overflow in the peripheral's memory. This is because the unexpected public key is always copied to a null address, which is beyond the control of the attacker. It is worthwhile to mention that this vulnerability can also lead to a deadlock. This is exemplified by our evaluation on the *CubiTag bluetooth tracker*. The product CubiTag does not properly handle hard faults and hence enters a deadlock state. This requires the user of the tracker to manually restart it.

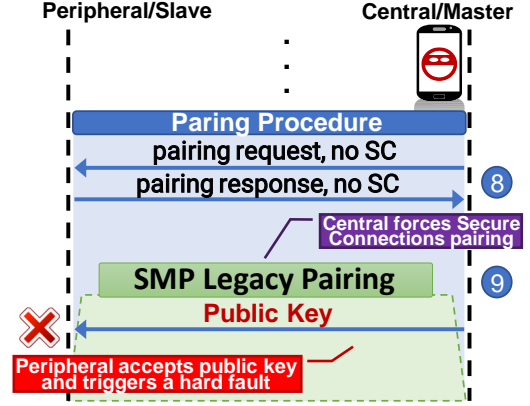

Figure 8: Unexpected Public Key Crash

6.7 Sequential ATT Deadlock (CVE-2019-19192)

In *STMicroelectronics WB55 SDK V1.3.0* and earlier, it is possible to deadlock the peripheral by sending just two consecutive ATT request packets in each connection event. Normally, each ATT request sent from a central device is followed by an ATT response from the peripheral. This happens in a time period multiple of the connection interval Δt . However, it is possible that a rogue central device sends multiple and consecutive ATT requests separated by the connection interval Δt (Figure 9). In such a case, the peripheral does not get sufficient time to respond to the first ATT request. The resulting behaviour is a fault in the coprocessor that runs the BLE SDK inside WB55, preventing certain BLE event flags to be cleared. This leads to a deadlock of the WB55 user code. Specifically, the faulty code potentially gets stuck in a *while* loop, which waits for a never finishing BLE event.

Impact: Similar to several other vulnerabilities discussed in this work, the exploitation of this vulnerability can leave the product in a deadlock state if a stability mechanism, such as the watchdog timer, is not employed by the vendor in product's firmware. If such a mechanism is present, the attack is still guaranteed to remotely restart the device.

Figure 9: Sequential ATT Deadlock

6.8 Invalid L2CAP fragment (CVE-2019-19195)

During the communication between the central device and peripheral, the Bluetooth 4.0-4.2 Core specification dictates that the minimum and maximum PDU size of the packets should be in the range 2-39 [11]. Packets outside this boundary should be discarded as they are invalid. However, we discovered that such is not the case for devices running *Microchip ATMSAMB11 BluSDK Smart* v6.2 and earlier. Following Figure 10, it was discovered that if an L2CAP PDU of length one is sent to the peripheral, then the device simply crashes.

Impact: The watchdog mechanism is enabled by default in the SDK, which reduces the risk for products relying on *AT-SAMB11* BLE solution to exhibit deadlock behaviour. Therefore, this vulnerability mostly affects the availability of the device by remotely restarting them.

Figure 10: Invalid L2CAP fragment

6.9 Key Size Overflow (CVE-2019-19196)

The Key Size Overflow vulnerability was found in all *Telink Semiconductor* BLE SDKs. This causes an overflow in the device memory, resulting in a crash. However, the problem that allows this vulnerability is a combination of multiple issue found during the pairing procedure of devices using Telink SMP implementation.

During the start of the pairing procedure, the central device sends a *Pairing request* packet containing the maximum allowed key size to be negotiated at the end of the pairing procedure. The maximum key size is standardised to be within 7 to 16 bytes and any deviation from that should be rejected with a *pairing failure* response. However, Telink peripheral actually accepts a *maximum encryption key size* up to 255 by answering the central device with a *paring response* instead. Despite this first problem, the peripheral rejects the pairing during at later exchanges of the pairing procedure without abnormal behaviour. The second and final problem that finally triggers the vulnerability, arises because the peripheral accepts the *LL Encryption procedure* to occur before the pairing procedure even starts, albeit failing at later stage.

Figure 11: Key Size Overflow

By combining the two mentioned problems it is possible to force the peripheral into allocating the over sized key buffer length which was negotiated during the *pairing request*. Depicted in Figure 11, the central device sends the invalid *pairing request*, waits for *pairing response* and sends an *encryption request*. The request is accepted and a buffer overflow occurs in peripheral's memory as its firmware tries to allocate the oversized key.

Impact: This vulnerability allows an attacker in radio to perform buffer overflow and crash Telink SoCs products with

pairing support enabled, which is a common practice in several BLE products. While this vulnerability doesn't expose easy control over the overflowed buffer, an exploit could be carefully constructed to overwrite memory contents adjacent to the key buffer if the memory layout of the product's firmware is known. In the worst case, it could be possible to overwrite buffers that store encryption nonce would allow the attacker to bypass encryption and leak user information.

6.10 Zero LTK Installation (CVE-2019-19194)

This critical vulnerability is a variation of one of the Key Size Overflow. It affects all products using Telink SMP implementation with support for secure connection enabled. It was verified that when the Telink peripheral accepts an out of order encryption request from the central, the encryption procedure is successful with a LTK which is zero. The LTK size, usually of 16 bytes, is agreed during the *pairing request/response* exchange.

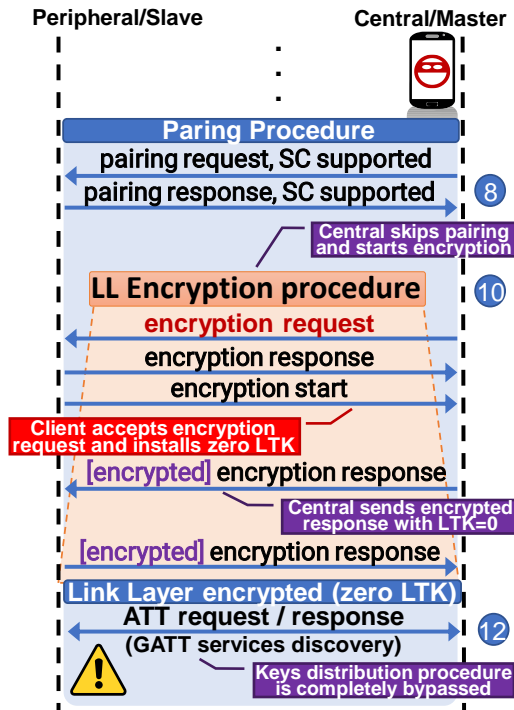

Figure 12: Zero LTK Installation

Following Figure 10, the rogue central sends a *pairing request* with secure connections pairing indicated and waits for a *pairing response*. Next, the central skips the secure connections pairing procedure and starts the encryption procedure by sending an *encryption request*. Due to the lack of validation in peripheral's implementation, the central receives an *encryption start* from the peripheral and sends an encrypted *encryption response* back. This response is relevant because the peripheral

validates it against the session key SK , which is derived from a valid LTK. Interestingly, the peripheral's LTK is initialized as zero. This allows the central to easily derive the SK to send the correct encrypted *encryption response* to the peripheral, hence successfully completing the encryption procedure. The SK (hiddenly mentioned in Bluetooth Core Specification as *sessionKey* [12]) is generated by the cryptographic function of Equation 1.

$$SK = AES_{ECB}(Key = LTK, Plaintext = SKD) \quad (1)$$

The Session Key Diversifier (SKD) is a random 16 byte number obtained via the *encryption request/response* exchange, therefore, guessing the correct LTK allows the central device to send an encrypted *encryption response* with a valid SK . As an aggravating factor, the *Keys distribution procedure* is completely bypassed after the attack is performed.

Impact: An attacker in Radio range can abuse this vulnerability to completely bypass security in a BLE products which rely in secure connections pairing to protect user privacy. Furthermore, device's functionalities which were only allowed to be accessed by an authorized user, can be trivially bypassed. In short, this vulnerability allows an attacker full communication control over a protected BLE application.

As a side note, this vulnerability only affects Telink devices that allows secure connection pairing. In reality, affected products that disable secure connections pairing (the currently secure BLE pairing mode) and enable only the insecure legacy pairing mode, are in fact more secure due to this vulnerability.
